Introduction to MASM

model: Model is an assembler directive. It is to inform the assembler that how many logical segments are used in the program

model tiny: In this model all the memory is treated as single segment

model small: In this model we have one code segment and one data segment

model large: In this model we have two code segments and two data segments

segment: Segment is an assembler directive. It is to tell the assembler that it is the starting of the logical segment

Ends: It is an assembler directive which informs the assembler that it is the end of the segment

Proc: Proc is used to call a subroutine

Assume: This makes the logical segment into physical segment

Masm: To convert the source code into object code and show errors

Syntax: masm filename.asm

Link: To convert the object file into executable file.

Syntax: link filename.obj

Debug: To run the program

Syntax: debug filename.exe

u: To unassembled the program

q: To quit the program

g: go(complete execution)

t: trace the program(step by step execution)

eds: To enter the data into data segment

dds: To display the data from data segment

The thumbnail shows a document cover with the title "Simple 8086 Assembly Language Program with Explanation" and a large "PDF" icon. Below the title, there is a small paragraph of text and a graphic with the words "ASSEMBLY CODE" in a stylized font. The document is attributed to "A Chandra Shaker" and includes social media sharing options.

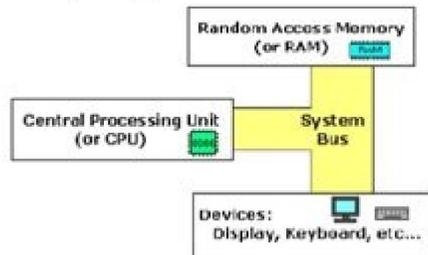

## 8086 assembler tutorial for beginners (part 1)

this tutorial is intended for those who are not familiar with assembler at all, or have a very distant idea about it. of course if you have knowledge of some other programming language (basic, c/c++, pascal...) that may help you a lot. but even if you are familiar with assembler, it is still a good idea to look through this document in order to study emu8086 syntax.

it is assumed that you have some knowledge about number representation (hex/bin), if not it is highly recommended to study [numbering systems tutorial](#) before you proceed.

### what is assembly language?

assembly language is a low level programming language. you need to get some knowledge about computer structure in order to understand anything. the simple computer model as i see it:

the **system bus** (shown in yellow) connects the various components of a computer. the **CPU** is the heart of the computer, most of computations occur inside the CPU. **RAM** is a place to where the programs are loaded in order to be executed.

### inside the cpu

8086 Assembler Tutorial for Beginners (Part 10)

## 8086 Assembler Tutorial for Beginners (Part 10)

### Macros

Macros are just like procedures, but not really. Macros look like procedures, but they exist only until your code is compiled, after compilation all macros are replaced with real instructions. If you declared a macro and never used it in your code, compiler will simply ignore it. [emu8086.inc](#) is a good example of how macros can be used, this file contains several macros to make coding easier for you.

Macro definition:

```
name MACRO [parameters,...]
    <instructions>
ENDM
```

Unlike procedures, macros should be defined above the code that uses it, for example:

```
MyMacro MACRO p1, p2, p3
    MOV AX, p1
    MOV BX, p2
    MOV CX, p3
ENDM
ORG 100h
MyMacro 1, 2, 3
MyMacro 4, 5, DX
RET
```

The above code is expanded into:

```
MOV AX, 00001h
MOV BX, 00002h
MOV CX, 00003h
```

BATCH : 2014-2018

What is assembly programming language used for. How to code assembly language. How to start assembly language programming. Is assembly language in demand. Assembly language programming 8086 tutorial pdf. How to make a programming language in assembly.

Each one uses 2 words - the first is the interruption manipulator segment, the second is the manipulator's address ... when a little is pushed to the right, it enters transport, and The previous transport value becomes the most left bit ... ADC or SBC adds or subtracts an extra 1 of the upper registration multiplication, unlike many 8-bit processors, 8086 has multiplication commands  $E \leftarrow \dots$ . For example, if we would like to access the memory at the fanic address 12345h (hexadecimal), we must define DS = 1230h and SI = 0045h. A high byte and a low byte ... from the  $z \ a \ p \ c$  det divide the number not signed ax or dx/ax by src. If it were 0, now it will be 1. Let's learn more about them soon! The segment records CS, DS and SS can not be defined by an immediate - we will have to carry another record and transfer the amount. We can specify -15 in our CODE ASM - the assembly will function the equivalent byte value. No worry about it now, but you will need it one day! If your mathematical is a pine and you can find out, see the Windows calculator, change to the 'programming mode' and have a bammel and hexadecimal view, so you can change no. One form for another! If you are a fan of Excel, look for the December and ten2hex functions ...  $N \ a \ E \ 0 \ \dots \ \dots$  not required to invert/turn all the pieces of these. The assembly converts it into a rich manner to this character. This makes it slower, but it doesn't make a difference for our programs! What's that 'bit' ... In this example, we'll read bytes with LodSB, then the words with the string lodsw. BP - Base pointer. The microcontroller or microprocessor can only understand the Paminary Language, such as 0 or 1  $\oplus$ , therefore, the assembly converts the assembly language to bimonal language and store the memory to perform the tasks. LOCK - - - - - DS load: si in ax or al. SHR (RIGHT CHANGE DIRECTION) - This changes the bits to the right, new upper bits are zero - any bits pushed out of the right is The same happens if we add from 2 to 254 ... they also h and l (BH, CL etc), let's give a value of 16 bits bx (666h) ... this command uses cx as a one Loop accountant ... For example, let's define 'Secondvariable' in +2 position, and a third called 'thirdivariable' in the +4 position so we can read its value with it or write it back. Address Indexed Plus (sum of two records) We can use the DI/SI records as a displacement with BX/BP - where the two records are added ... Loop/Looplabel - - - - - SRC moves a value of the SRC source to destination destin mov ax, bx - - - - - movsb/movsw moves a byte or word of ds: si to es: di. (Like Z80 LDIR) This command can be combined with the repeated command representative to repeat the CX Times. Zero flag ( $\oplus$  Equal) the zero flag is defined when the result of a command is zero ... d flag will be defined as 1. cx will be reduced, and a heel for the specified role will occur if the cx It's not zero ... Therefore, you should try to maintain variables  $\hat{c}$  ught in the records. We can push the pile and go back to the AX and vice-versa in the example, pushed all the flags with the pushf and put them back to the ax, we were able to push and put the flags on the battery. The simple model I see: the system bus (shown in yellow) connects the components of a computer. Commands, labels and calls let's take a look at a simple program! ... CLC - - - - - Cld Clean the direction flag. Again, as the stack moves to the transfers, the values in the battery are reversed pushing flags and transferring flags to the accumulator! We can push all records this way, but sometimes we need to push the flags ... Bx is not affected by testnedcall2 due to BX pop in TestnedCall1, you should be careful to remove everything your subroutine put in Before the return ... These 'segment records' are added to the 20 main bits of the address address - - - - - dddddddddddddddd ... rep stosh - - - - - Sun desta, src subtractor src from destro. They will be the same for loop counters and things like that. This allows chewing interruptions. We can use bx+di, dx+si, bp+di, bxs+di that we read in the addresses in the test data resulting from the BP+di calculation, beware ... grain assembly we need not to worry that it is not up to it ... Remember the strange records of oneself and I have seen in UNGCIO, which do not work as the general? Resq 1 alloca 8 bytes. I SIGNALIZE will be defined as 0. LDS BX, TESTPOINTER AX, BX, CX, DX, SI, DI - - - - - SRC Load the Effective Address SRC in Reg. FI ... the right 1234h is that the source 1234h is moved to the AX record, we finally call the Domonitorax - it will show the result on the screen. When we use a RET instruction, we are effectively removing the battery program counter (IP) ... SHL AX, 1 0 - - - C SHR Destin, the count changes the right bits in the destination of DestinE 0 by counting. LIARD 2 - Address modes Our commands used only fixed immediate values or other records to now ... Bit change also allows mere multiplication, the change to the left effectively doubles a value, the change to the right effectively halves. Diverse with flags! To understand conditional heels, we need to understand the flags of the 8086 processor ... here is the result, it is of course ... di points to the following byte after the end of the routine ... We load in 3 bytes and then, 3 words XLAT - Translate XLAT is a translation command - it uses a search table in [ds: bx] and loads al with the value in displacement al (al = [ds: bx+al]) In this example we use XLAT to convert a number to a pair of snacks with this number ... Usually you can not access these records directly, and write back the same way ... the divide by zero causes 0 and block the mother. STI 1 - - - - - Stosh Stosh Store Ax or Al to ES: di. In this We will push 4 bytes (2 words) to the stack, and the function will load to CX and DX, then return ... al = al+(ah\*10), ah = 0, shr ax, 1 0 - - - C STC Define the transport flag. Specifies to create the EXE file of the EXE -DXXX = Y ... The programming of the not-one assembly is very important for the design of the based system not used to access the processor instructions for Manipulate the hardware. It is a very primitive language of motion is used to make an efficient way that consumes less of relief cycles and takes less memory compared to the high -rally programming language. TestnedCall2 will be executed, your return address will be pressured ... the declaration will remove the 4 bytes cx and dx receive the values pushed to the stack macros. I will not cover those here ... we will use the monitor function to show the value of records and flags. This defines the zero flag in the same way as 'sub-desto, src' would do. Ret - - - - - RD Dest, Count Gira Bits at the destination of the destination 4 left by Bits Rol Mach 1 0 - - - C Salf Store Ah for the flags. And in some cases a command has two possible names as a convenience for the programmer ... DI - Registration of destination. A leap! Upon a call from a call, it never returns ... the other is 'overflowing' ... (these are defined during vain commands, and their meaning will vary in some cases ... the second call of TestnedCall2 will cause your return address to replace the first (as was launched in the previous return) the end result! For example ... In fact, the call declarations also use the pile ... it is used for depuration if we have problems -fo ... sword (signed double word) alloca signed of  $e \ \hat{c} \ 2,147,483,648 + 2,147,483,647$ . Loop/looplabel - - - - - loopnz add loopnz addr decrease cx and heel to add if it is not zero and the flag is not defined. Registration Signs - Determines the current state of the processor. Finally, we have the JMP command ... This example sends data to port 42h (the -speaker) ... a rich riparian rod - this provides us with some support tools and includes a common bitmap source. In this case, we reverse the pop order of BX and AX and BX were reversed after the pops you don't want to do by accident - but there will be times when you will want to do it from you! The nestled battery pushes because of the way the stack works, we are effectively nestling the push at the battery ... Let's make a clear example to really show it ... First we will reverse 1234h, then 5678h, then 9abc then 'then, I'll take them all out of the pile, the three values are pushed to the stack and they retreated intact ... We can put items in it, but only take the upper item ... 0fh ... also note that cx no E zero sca range - scan for string scaes scanning a string and comparing with cx (or al), we can use repz to scan the bytes to do not match AX/al set the direction flag E the with SdA  $\hat{c}$  so that we go back to the TRANS ... The same is for 3 other records, 'h' is to high and 'l' is low part. This will subtract and add a value to the AX ... we can get the segment with the displacement declaration now we have the records configured ... if there is a number P/R P = 1 (pair) Overflow flag Testing is used to verify that a signed record has become invited ... Signal bit test, we can also test the signal bit - if 0 Bit top of the last mathematical operation for 0, the value will be positive - if it is the value is negative. Sub Ax, Bx 0 S Z A P C TEST DEST, SRC TEST DEST, DEFINING THE SIGNATORS IN THE SAME WAY AS AN EVIDGE 'AND SRC' WOULD HAVE IT. We copied 3 bytes from the source to Destination in the first example in the second screen capture that I enabled the STD, reversing the procedure, and we use the Stovs representative to copy the AX to an interval interval 3 CMPS Words - Compare String CMPSB/W Compare two sequels, one in DS: Si and one in ES: DI, we need to use repz or repz to repeat it - and define cx. Shl and salt do the same thing! No matter what you use - so you don't worry! Define and clean flags, we analyze vain tricks with flags in previous literatures, but we don't cover the range of commands to define and clean the flags arbitrarily ... C flag will be defined as 1. Let's go them to the work! String commands perform a sequence of action in one range - the function varies according to the command ... CPU makes a clearance of the fan of fanic multiplying the segment registration by 10h and adding General Proposal Record (1230h \* 10h + 45h = 12345h). The address formed with 2 records is called effective address. This makes the way more rude, and it is not called, but greater, as there will be a double of the call. This treats the al as a compressed binary decimal. C flag will be defined as zero. The best thing is trying! Try to change the examples and see what works and what doesn't work! Lion 3 - loops, jumps and conditions that we analyze the simple mathematics and approaching ... STD D - - - - - defines the interrupted activation signal. E 0, Dword, dl (doubleword = 4 bytes), allocating n. In computers, the kilo is 1024, because  $2^{10} = 1024$  The 8086 is very old now, but it is the basis of all the computers we have today ... because the records are located within the CPU, they are much harsher than the memory. A basic understanding of any of the programming languages will help you understand the concepts of programming of the assembly and quickly move to the learning range. A record is the main part of the microprocessors and controllers located in the memory that provides a more to collect and store the data. Loopz also end if the zero flag is defined loopnz also finish if the zero flag is not set, it is important important. This loop itself does not change the zero flag (Z) - therefore mathematical operation for 0, the value will be positive - if it is the value is negative. Sub Ax, Bx 0 S Z A P C TEST DEST, SRC TEST DEST, DEFINING THE SIGNATORS IN THE SAME WAY AS AN EVIDGE 'AND SRC' WOULD HAVE IT. Define and clean flags, we analyze vain tricks with flags in previous literatures, but we don't cover the range of commands to define and clean the flags arbitrarily ... C flag will be defined as 1. Let's go them to the work! String commands perform a sequence of action in one range - the function varies according to the command ... CPU makes a clearance of the fan of fanic multiplying the segment registration by 10h and adding General Proposal Record (1230h \* 10h + 45h = 12345h). The address formed with 2 records is called effective address. This makes the way more rude, and it is not called, but greater, as there will be a double of the call. This treats the al as a compressed binary decimal. C flag will be defined as zero. The best thing is trying! Try to change the examples and see what works and what doesn't work! Lion 3 - loops, jumps and conditions that we analyze the simple mathematics and approaching ... STD D - - - - - defines the interrupted activation signal. E 0, Dword, dl (doubleword = 4 bytes), allocating n. In computers, the kilo is 1024, because  $2^{10} = 1024$  The 8086 is very old now, but it is the basis of all the computers we have today ... because the records are located within the CPU, they are much harsher than the memory. A basic understanding of any of the programming languages will help you understand the concepts of programming of the assembly and quickly move to the learning range. A record is the main part of the microprocessors and controllers located in the memory that provides a more to collect and store the data. Loopz also end if the zero flag is defined loopnz also finish if the zero flag is not set, it is important important. This loop itself does not change the zero flag (Z) - therefore mathematical operation for 0, the value will be positive - if it is the value is negative. Sub Ax, Bx 0 S Z A P C TEST DEST, SRC TEST DEST, DEFINING THE SIGNATORS IN THE SAME WAY AS AN EVIDGE 'AND SRC' WOULD HAVE IT. We copied 3 bytes from the source to Destination in the first example in the second screen capture that I enabled the STD, reversing the procedure, and we use the Stovs representative to copy the AX to an interval interval 3 CMPS Words - Compare String CMPSB/W Compare two sequels, one in DS: Si and one in ES: DI, we need to use repz or repz to repeat it - and define cx. Shl and salt do the same thing! No matter what you use - so you don't worry! Define and clean flags, we analyze vain tricks with flags in previous literatures, but we don't cover the range of commands to define and clean the flags arbitrarily ... C flag will be defined as 1.
